The quantitative quality of lipid-cholesterol interactions in atomistic resolution models will be determined against NMR and scattering data.

INTRODUCTION

Importance of phospholipid cholesterol interactions in cellular membranes have been reckognized for long time [?]. Various ideas about lateral heterogeneities driven interactions between cholesterol, phosphatidylcholine other other membrane lipids has been proposed [?]. Especially coexistence of liquid-ordered and liquid-disordered phases in PC-cholesterol mixtures has been suggested to be important in biological lipid membranes [?].

Phase diagram of PC lipid cholesterol systems, including lo-ld coexistence can be explained by simple models where cholesterol is assumed to induce order in neighboring lipids [?]. This is important achievement in order to understand biomembrane organization. However, also more detailed interactions driving interactions between cholesterol and other membrane lipid molecules are often relevant. Several attempts to understand these interactions have been made by using classical molecular dynamics simulations [?]. These simulations give atomistic resolution information, which not directly accessible with any other techinique. However, the simulations often suffer from inaccuracies in force field descriptions. Acyl chain region is usually well described in molecular dynamics simulation models, which is not the case for glycerol backbone and headgroup [?]. The same applies to the systems with cholesterol. Practically all simulation models qualitatively reproduce the condesing due to cholesterol, observed as increase in acyl chain order parameters and decrease of area per molecule. However, the some models significantly overestimate the changes in headgroup due to the addition of cholesterol [?].

On the other hand, detailed analysis of lateral organization of lipid-cholesterol mixtures reveal significant differences between different models. For example, significant angular organization of lipids around cholesterol was observed in simulations with Berger Hjtje models, while CHARMM36 simulations did not show such behaviour.

METHODS

X-ray scattering experiments

This folder contains SAXS data on POPC multilamellar vesicles (MLVs) at various cholesterol concentrations. Data have been obtained at the EMBL BioSAXS beamline (Hamburg) using 20 keV photons, T = 27C. Data were analyzed in terms of the SDP-GAP model described in Heftberger et al., J. Appl. Cryst. 2013 and Heftberger et al. Biophys. J. 2015. Data from MLVs are a convolute of structure factor (the crystalline lattice) and form factor. By fitting the scattered intensity data we obtain both contributions. Here we posted only form factors (ASCII format). For information on the quality of the fit we also give plots of the fitted intensity data. The electron density profile has been modelled in terms of the SDP model (see papers by Kucerka and coworkers), that is volume distribution functions are modelled by individual Gaussians or error functions. Cholesterol is also accounted for by two Gaussians. This model has been proposed by Jianjun Pan (USF, Tampa, FL), but is to the best of our knowledge not published (see also PhD Thesis by Peter Heftberger). Additional figures show the volume distribution functions and the resulting electron density profiles.

Molecular dynamics simulations

COMPARISON OF ACYL CHAIN ORDER PARAMETERS BETWEEN EXPERIMENTS AND SIMULATIONS

Order parameters from simulations and experiments for acyl chains of 1-palmitoyl-2-oleoylphosphatidylcholine (POPC) are shown in Fig. 1.

The order parameter changes as a function of cholesterol for each segment are shown in Fig. 2 (currently only sn-1).

COMPARISON OF FORM FACTORS BETWEEN EXPERIMENTS AND SIMULATIONS

The form factors calculated from different simulations with different cholesterol content are shown in Fig. 3.

CONCLUSIONS

SUPPLEMENTARY INFORMATION

CHARMM36 results from different simulation packages

The results from CHARMM36 model for lipid bilayers from different simulation packages have been reported to give different results in the literature [19, 20]. The results are mainly dependent on different Lennart-Jones cut–off settings, but all the details are not quite understood. In this work we use the results from Gromacs 5 with settings suggested to be optimal by Gromacs webpage. We also compared the results from Gromacs 5 with these settings to the results simulated with NAMD, OpenMM and literature values. The comparison is shown in Fig. 4
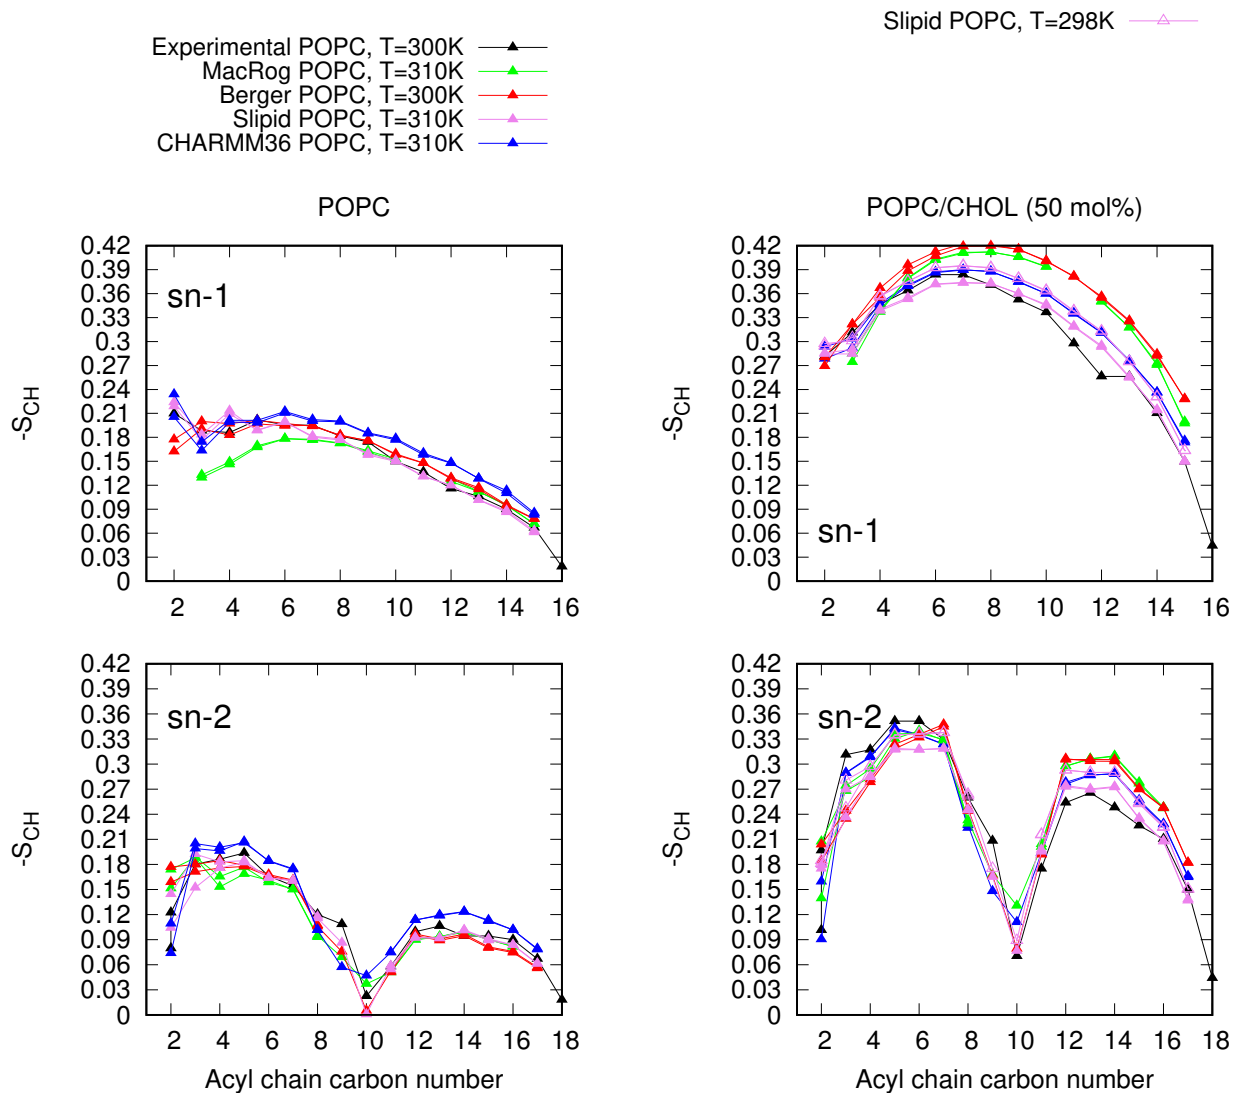

Slipid POPC, T=298K

FIG. 1: Order parameters from simulations and experiments for acyl chains of 1-palmitoyl-2-oleoylphosphatidylcholine (POPC).

1.Why are the order parameters of CHARMM36 too large compared to simulations even without cholesterol? Discussion in

https://github.com/NMRLipids/NmrLipidsCholXray/issues/4

2.Why there is decrease in order parameters towards beginning of acyl chain in MacRog model without cholesterol?

3.Do the results suggests that condensation effect is too strong in MacRog and Berger models? Discussion in https://github.com/NMRLipids/NmrLipidsCholXray/issues/5
